

NCV7708E

Double Hex Driver

The NCV7708E is a fully protected Hex-Half Bridge-Driver designed specifically for automotive and industrial motion control applications. The six low and high side drivers are freely configurable and can be controlled separately. This allows for high side, low side, and H-Bridge control. H-Bridge control provides forward, reverse, brake, and high impedance states. The drivers are controlled via a standard SPI interface.

Features

- Ultra Low Quiescent Current Sleep Mode
- Six Independent High-Side and Six independent Low-Side Drivers
- Integrated Freewheeling Protection (LS and HS)
- Internal Upper and Lower Clamp Diodes
- Configurable as H-Bridge Drivers
- 0.5 A Continuous (1 A peak) Current
- $R_{DS(on)} = 0.8 \Omega$ (typ)
- 5 MHz SPI Control
- SPI Valid Frame Detection
- Compliance with 5 V and 3.3 V Systems
- Overvoltage Lockout
- Undervoltage Lockout
- Fault Reporting
- Current Limit
- Overtemperature Protection
- Internally Fused Lead in SOIC-28
Packaged for Better Thermal Performance
- These are Pb-Free Devices*

Typical Applications

- Automotive
- Industrial
- DC Motor Management

PIN DESCRIPTION

Pin No.	Symbol	Description
1	OUTL5	Output Low Side 5. Open drain output driver with internal reverse diode.
2	OUTH5	Output High Side 5. Open source output driver with internal reverse diode. Drain connected to VS2.
3	OUTH4	Output High Side 4. Open source output driver with internal reverse diode. Drain connected to VS2.
4	OUTL4	Output Low Side 4. Open drain output driver with internal reverse diode.
5	VS2	Voltage Power Supply input for the High-Side Output Drivers 4, 5, and 6.
6	GND	Ground
7	GND	Ground
8	GND	Ground
9	GND	Ground
10	VS1	Voltage Power Supply input for the High-Side Output Drivers 1, 2, and 3, All six low side pre-drivers, and all six charge pumps.
11	OUTL3	Output Low Side 3. Open drain output driver with internal reverse diode.
12	OUTH3	Output High Side 3. Open source output driver with internal reverse diode. Drain connected to VS1.
13	OUTH2	Output High Side 2. Open source output driver with internal reverse diode. Drain connected to VS1.
14	OUTL2	Output Low Side 2. Open drain output driver with internal reverse diode.
15	OUTH1	Output High Side 1. Open source output driver with internal reverse diode. Drain connected to VS1.
16	OUTL1	Output Low Side 1. Open drain output driver with internal reverse diode.
17	EN	Enable. Input high wakes the IC up from a sleep mode.
18	SO	Serial Output. 16 bit serial communications output.
19	V _{CC}	Power supply input for Logic.
20	GND	Ground
21	GND	Ground
22	GND	Ground
23	GND	Ground
24	CSB	Chip Select Bar. Active low serial port operation.
25	SCLK	Serial Clock. Clock input for use with SPI communication.
26	SI	Serial Input. 16 bit serial communications input.
27	OUTL6	Output Low Side 6. Open drain output driver with internal reverse diode.
28	OUTH6	Output High Side 6. Open source output driver with internal reverse diode. Drain connected to VS2.

MAXIMUM RATINGS

Rating	Value	Unit
Power Supply Voltage (VS1, VS2) (DC) (AC), t < 500 ms, I _{vsx} > -2 A	-0.3 to 40 -1.0	V
Output Pin OUTHx (DC) (AC – inductive clamping)	-0.3 to 40 -8.0	V
Output Pin OUTLx (DC) (AC), t < 500 ms, I _{OUTLx} > -2 A (AC Inductive Clamping)	-0.3 to 34 -1.0 48	V
Pin Voltage (Logic Input pins, SI, SCLK, CSB, SO, EN, V _{CC})	-0.3 to 7.0	V
Output Current (OUTL1, OUTL2, OUTL3, OUTL4, OUTL5, OUTL6, OUTH1, OUTH2, OUTH3, OUTH4, OUTH5, OUTH6) (DC) V _{ds} = 12 V (DC) V _{ds} = 20 V (DC) V _{ds} = 40 V (AC) V _{ds} = 12 V, (50 ms pulse, 1 s period) (AC) V _{ds} = 20 V, (50 ms pulse, 1 s period) (AC) V _{ds} = 40 V, (50 ms pulse, 1 s period)	-1.5 to 1.5 -0.7 to 0.7 -0.25 to 0.25 -2.0 to 2.0 -0.9 to 0.9 -0.3 to 0.3	A
Electrostatic Discharge, Human Body Model, VS1, VS2, OUTx	4.0	kV
Electrostatic Discharge, Human Body Model, all other pins	2.0	kV
Electrostatic Discharge, Machine Model	200	V
Electrostatic Discharge, Charged Device Model	1.0	kV
Operating Junction Temperature	-40 to 150	°C
Storage Temperature Range	-55 to 150	°C
Moisture Sensitivity Level	MSL 3	–
Peak Reflow Soldering Temperature: Pb-Free, 60 to 150 seconds at 217°C (Note 1)	260	°C

Stresses exceeding Maximum Ratings may damage the device. Maximum Ratings are stress ratings only. Functional operation above the Recommended Operating Conditions is not implied. Extended exposure to stresses above the Recommended Operating Conditions may affect device reliability.

- For additional information, please see or download the ON Semiconductor Soldering and Mounting Techniques Reference Manual, SOLDERM/D.

RECOMMENDED OPERATING CONDITIONS

Rating	Value		Unit
	Min	Max	
Digital Supply Input Voltage (V _{CC})	3.0	5.5	V
Battery Supply Input Voltage (V _S)	5.1	28	V
DC Output Current (D _x , S _x)	–	0.5	A
Junction Temperature (T _J)	-40	125	°C

THERMAL CONDITIONS

8. Not tested in production

9. This is the minimum time the user must wait between SPI commands.

Figure 2. SPI Timing Diagram

SPI Communication

Standard 16-bit communication has been implemented for the communication of this IC to turn drivers on and off, and to report faults. (Reference the SPI Communication Frame Format Diagram). The LSB (Least Significant Bit) is clocked in first.

Communication is implemented as follows:

1. CSB goes low to allow serial data transfer.
2. A 16 bit word is clocked (SCLK) into the SI (serial input) pin. The SI input signal is latched on the falling edge of SCLK.

3. CSB goes high to transfer the clocked in information to the data registers.
(Note: SO is tristate when CSB is high.)
4. The SI data will be accepted when a valid SPI frame is detected. A valid SPI frame consists of the above conditions and a complete set of multiples of 16 bit words.

Figure 3. SPI Communication Frame Format

The table below defines the programming bits and diagnostic bits. Fault information is sequentially clocked out the SO pin of the NCV7708E as programming information is clocked into the SI pin of the device. Daisy chain

communication between SPI compatible IC's is possible by connection of the serial output pin (SO) to the input of the sequential IC (SI).

DETAILED OPERATING DESCRIPTION

General

The NCV7708E Double Hex Driver provides drive capability for 3 independent H-Bridge configurations, or 6 High Side configurations with 6 Low Side configurations, or any combination of arrangements. Each output drive is characterized for a 500 mA load and has a typical 1.0 A surge capability (at 12 V). Strict adherence to integrated circuit die temperature is necessary. Maximum die temperature is 150°C. This may limit the number of drivers enabled at one time. Output drive control and fault reporting is handled via the SPI (Serial Peripheral Interface) port.

An Enable function (EN) provides a low quiescent sleep current mode when the device is not being utilized. No data is stored when the device is in sleep mode. A pull down current source is provided on the EN input to ensure the device is off if the input signal is lost. Pull down current sources are also provided on the SI and SCLK inputs. A pull up current source is provided for the CSB input for the same reason. A loss of signal pulls the CSB input high to stop any spurious signals into the SPI port.

Power Up/Down Control

An under voltage lockout circuit prevents the output drivers from turning on unintentionally. This control is provided by monitoring the voltages on the VS1, VS2, and V_{CC} pins. Each analog power pin (VS1 or VS2) powers their respective output drivers (VS1 powers OUTH1, OUTH2, OUTH3, all 6 charge pumps and all 6 low-side pre-drivers, VS2 powers OUTH4, OUTH5, and OUTH6). All drivers are

initialized in the off (high impedance) condition, and will remain off regardless of the status of V_{CC}. This allows power up sequencing of V_{CC}, VS1, and VS2 up to the user. The voltage on VS1 and VS2 should be operated at the same potential.

A built-in hysteresis on the under voltage threshold is included to prevent an unknown region on the power pins. After a device has powered up and the output drivers are allowed to turn on, the output drivers will not turn off until the voltage on the supply pins is reduced from the initial under voltage threshold, or if shut down by either a SPI command or a fault condition.

Internal power-up circuitry on the logic supply pin supports a smooth turn on transition. V_{CC} power up resets the internal logic such that all output drivers will be off as power is applied. Exceeding the under voltage lockout threshold on V_{CC} allows information to be input through the SPI port for turn on control. Logic information remains intact over the entire VS1 and VS2 voltage range.

Current Limitation

Input bit 13 (OCD) controls the action of driver shutoff during current limit. With a 0 for bit 13, there is no driver shutoff, and the drivers current limit at 3 A. With a 1 for input bit 13, the output drivers shut off when the shutdown threshold current is passed. Devices can be turned back on via the SPI port. Note: high currents could cause a high rise in die temperature. Devices will not turn on if the die temperature exceeds the thermal shutdown temperature.

Over Current Detection Shut Down

OCD Input Bit 13	OUTx OCD Condition	Output Data Bit 13 Over Load Detect (OLD) Status	OUTx Status	Current Limit of all Drivers
0	0	0	Unchanged	3 A
0	1	1 (Need SRR to reset)	Unchanged	3 A
1	0	0	Unchanged	3 A
1	1	1 (Need SRR to reset)	OUTx Latches Off (Need SRR to reset)	3 A

Under Load Detection

The under-load detection is accomplished by monitoring the current from each output driver. A minimum load current (this is the maximum open circuit detection threshold) is required when the drivers are turned on. If the under-load circuit detection threshold has been crossed for more than

the under-load delay time, the bit indicator (output bit #14) for open circuit will be set to a 1. In addition, the offending driver will be turned off only if input bit 14 (ULD) is set to 1 (true).

Under Load Detection Shut Down

ULD Input Bit 14	OUTx ULD Condition	Output Data Bit 14 Under Load Detect (ULD) Status	OUTx Status
0	0	0	Unchanged
0	1	1 (Need SRR to reset)	Unchanged
1	0	0	Unchanged
1	1	1 (Need SRR to reset)	OUTx Latches Off (Need SRR to reset)

Over Voltage Shutdown

Over voltage shutdown circuitry monitors the voltage on the VS1 and VS2 pins. When the Over-voltage Threshold voltage level has been breached on both or either one of the VSx supply inputs, output bit 15 will be set and, if input bit 15 (OVLO) is set to 1, all outputs will turn off. Turn on/off

status is maintained in the logic circuitry. When proper input voltage levels are re-established, the programmed outputs will turn back on. Over-voltage shutdown can be disabled by using the SPI input bit 15 (OVLO = 0).

Over Voltage Lock Out (OVLO) Shut Down

OVLO In-put Bit 15	VSx OVLO Condition	Output Data Bit 15 Power Supply Fail (PSF) Status	OUTx Status
0	0	0	Unchanged
0	1	1 (Need SRR to reset)	Unchanged
1	0	0	Unchanged
1	1	1 (Need SRR to reset)	All Outputs Off (Remain off until VSx is out of OVLO)

Thermal Shutdown

Six independent thermal shutdown circuits are featured (one common sensor for each HS and LS transistor pair). Each sensor has two levels, one to give a Thermal Warning (TW) and a higher one, Over Temperature, which will shut the drivers off. When the part reaches the temperature point of Thermal Warning, the output data bit 0 (TW) will be set to a 1, and the outputs will remain on. With one or more sensors detecting the over temperature level, all channels will be turned off simultaneously. All outputs will return to normal operation when the part thermally recovers (Thermal toggling), because the over temperature shutdown does not change the actual channel selection. The output data bit 0, Thermal Warning, will latch and remain set, even after cooling, and is reset by using a software command to input bit 0 (SRR). Since thermal warning precedes a thermal shutdown, software polling of this bit will allow for load

control and possible prevention of thermal shutdown conditions.

Thermal warning information can be retrieved immediately without performing a complete SPI access cycle. Figure 4 below displays how this is accomplished. Bringing the CSB pin from a 1 to a 0 condition immediately displays the information on the output data bit 0, thermal warning, even in the absence of a SCLK signal. As the temperature of the NCV7708E changes from a condition from below the thermal warning threshold to above the thermal warning threshold, the state of the SO pin changes and this level is available immediately when the CSB goes to 0. A 0 on SO indicates there is no thermal warning, while a 1 indicates the IC is above the thermal warning threshold. This warning bit is reset by using the input data bit 0, SRR.

Figure 4. Access to Temperature warning information shows the thermal information is available immediately with activation of the CSB signal without having to toggle the SCLK line.

Applications Drawing

The applications drawing below displays the range with which this part can drive a multitude of loads.

1. H-Bridge Driver configuration
2. Low Side Driver
3. High Side Driver

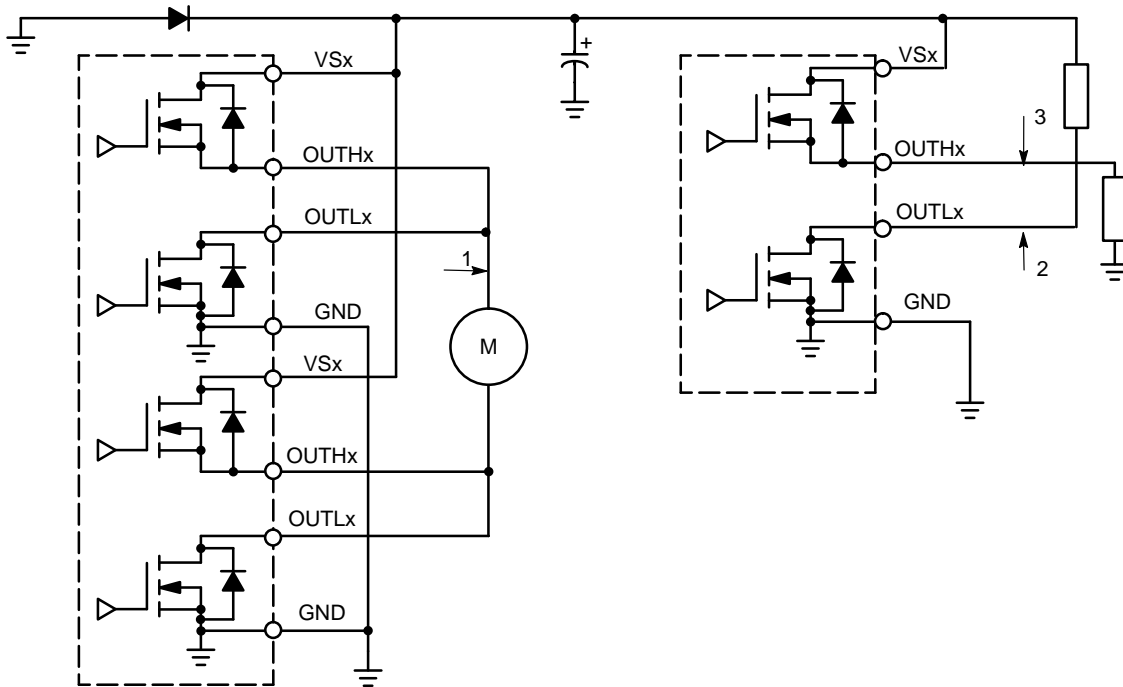

Figure 5. Application Drawing

Any combination of motors and high side drivers can be designed in. This allows for flexibility in many systems.

H-Bridge Driver Configuration

The NCV7708E has the flexibility of controlling each driver independently. When the device is set up in an H-Bridge configuration, the software design has to take care of avoiding simultaneous activation of connected HS and LS transistors. Resulting high shoot through currents could cause irreversible damage to the device.

Overvoltage Clamping – Driving Inductive Loads

To avoid excessive voltages when driving inductive loads in a single-side-mode (LS or HS switch, no freewheeling path), the NCV7708E provides internal clamping diodes. Thus any load type can be driven without the requirement of external freewheeling diodes. Due to high power dissipation during clamping, the maximum energy capability of the driver transistor has to be considered.

Bold face items in the Cauer network above, represent the package without the external thermal system. The Bold face items in the Foster network are computed by the square root of time constant $R(t) = 28.4 * \sqrt{\text{time}(\text{sec})}$. The constant is derived based on the active area of the device with silicon and epoxy at the interface of the heat generation.

The Cauer networks generally have physical significance and may be divided between nodes to separate thermal behavior due to one portion of the network from another. The Foster networks, though when sorted by time constant (as above) bear a rough correlation with the Cauer networks, are really only convenient mathematical models. Both Foster and Cauer networks can be easily implemented using

circuit simulating tools, whereas Foster networks may be more easily implemented using mathematical tools (for instance, in a spreadsheet program), according to the following formula:

$$R(t) = \sum_{i=1}^n R_i (1 - e^{-t/\tau_{i,j}})$$
